Overview

- Problem Statement
- Background Information
- Design
- Synthesis of Nanoparticles
- Characterization
- Entrapment Efficiency
- Reaction Testing
- Budget
- Questions

Problem Statement

- To provide a safe, yet more efficient method of protection from vesicants that improves the operational effectiveness of first-responders and soldiers
- Design a nanoparticle system that will absorb, entrap, and deactivate target vesicants

Background Information

History of Use

- Mustard agent use in war
 - Easy to make, cheap
- Potential Users
 - First responders
 - Firefighters, Police
 - Military

[1]

Need for a NP System

- Prior products
 - Application issues
 - Not prophylactic
 - Problems with military equipment compatibility

[2]

[3]

Design Overview

Selection of nanoparticle system materials

Nanoparticle synthesis method and testing plan formation

Synthesize nanoparticle system

Characterize nanoparticle system

Determine entrapment efficiency

Verify entrapment/deactivation of 2-CEES

Design Schematic

Legend

PLGA
nanoparticle
(polymer)

TOA or DIEA
(deactivating
chemical)

PVA
(surfactant)

2-CEES
(vesicant
simulant)

Measurable Objectives

Characterization

- Size
 - >200 nm to prevent endocytosis
- Polydispersity Index (PDI)
 - Monodisperse <0.1
- Zeta Potential
 - ± 30 mV for moderate stability

Entrapment Efficiency

- >70% deactivating chemical entrapped within nanoparticle

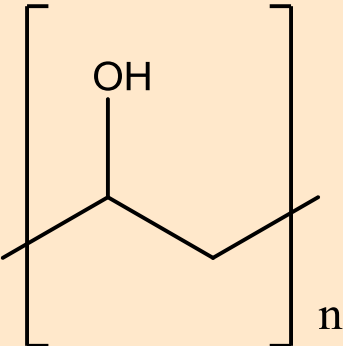

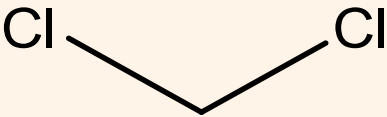

Reaction Testing

- NPs instantaneously respond to presence of vesicant
- Entrapment and deactivation of vesicant
- Loaded NP deactivation occurs faster than free chemical reaction with vesicant

Design Justification

Component	Justification
<p>Polymer: poly D, L-lactide-co-glycolide (PLGA)</p>	<p>FDA approved for human therapy Well-characterized polymer Biocompatibility Biodegradability Degradation sub products are non-toxic</p> <div data-bbox="865 415 1870 682" data-label="Chemical-Block"> <p style="text-align: center;"> <chem>CC(C(=O)O)C(=O)O</chem> + <chem>OCC(=O)O</chem> </p> <p style="text-align: center;"> PLGA $\xrightleftharpoons{H^+}$ Lactic Acid + Glycolic Acid </p> <p style="text-align: center;"> Metabolic Pathways [4] </p> </div>
<p>Deactivating Chemical: -Trioctylamine (TOA) -Diisopropyl ethyl amine (DIEA)</p>	<p>Hydrophobic Reactive for our purposes (Non-nucleophilic base) Will not bond with the PLGA to our detriment</p> <div data-bbox="531 906 1439 1299" data-label="Chemical-Block"> <p style="text-align: center;"> <chem>CCCCCCCCN(CCCCCCCC)CCCCCCCC</chem> </p> <p style="text-align: center;">TOA</p> <p style="text-align: center;"> <chem>CC(C)CN(C(C)C)CC</chem> </p> <p style="text-align: center;">DIEA</p> </div>

Design Justification

Component	Justification
Surfactant: Polyvinyl alcohol (PVA)	<p>Water soluble Excellent emulsifying properties Reduces surface tension Aids in the solubility of 2-CEES; drives reaction between 2-CEES & TOA</p>  <p>The diagram shows the chemical structure of Polyvinyl alcohol (PVA) as a repeating unit enclosed in large square brackets with a subscript 'n'. The structure consists of a three-carbon chain. The first carbon is bonded to a hydroxyl group (OH) pointing upwards. The second carbon is bonded to a hydrogen atom (not explicitly shown but implied by the valency). The third carbon is bonded to a hydrogen atom (not explicitly shown but implied by the valency). The bonds from the first and third carbons extend through the brackets to indicate the polymer chain continues.</p>
Solvent: Dichloromethane (DCM)	<p>Ability to dissolve all other NP synthesis components Not reactive with TOA Evaporates easily due to its relatively low boiling point (39.6°C)</p>  <p>The diagram shows the chemical structure of Dichloromethane (DCM) as a V-shaped molecule. A central carbon atom is bonded to two chlorine atoms (Cl) at the ends of the V-shape.</p>

Synthesis of PLGA Nanoparticles

- Emulsion-Solvent Evaporation Technique
 - Top-down technique
 - Biodegradable nanoparticles with entrapped hydrophobic compounds
- Preparation of stock solutions
 - Time efficient
 - More consistent
- Synthesis of blank NPs
 - Provides a control
- Synthesis of loaded NPs
 - Loaded with deactivating agent
 - TOA or DIEA

Synthesis of PLGA Nanoparticles

Mixing of continuous and discontinuous phase during sonication

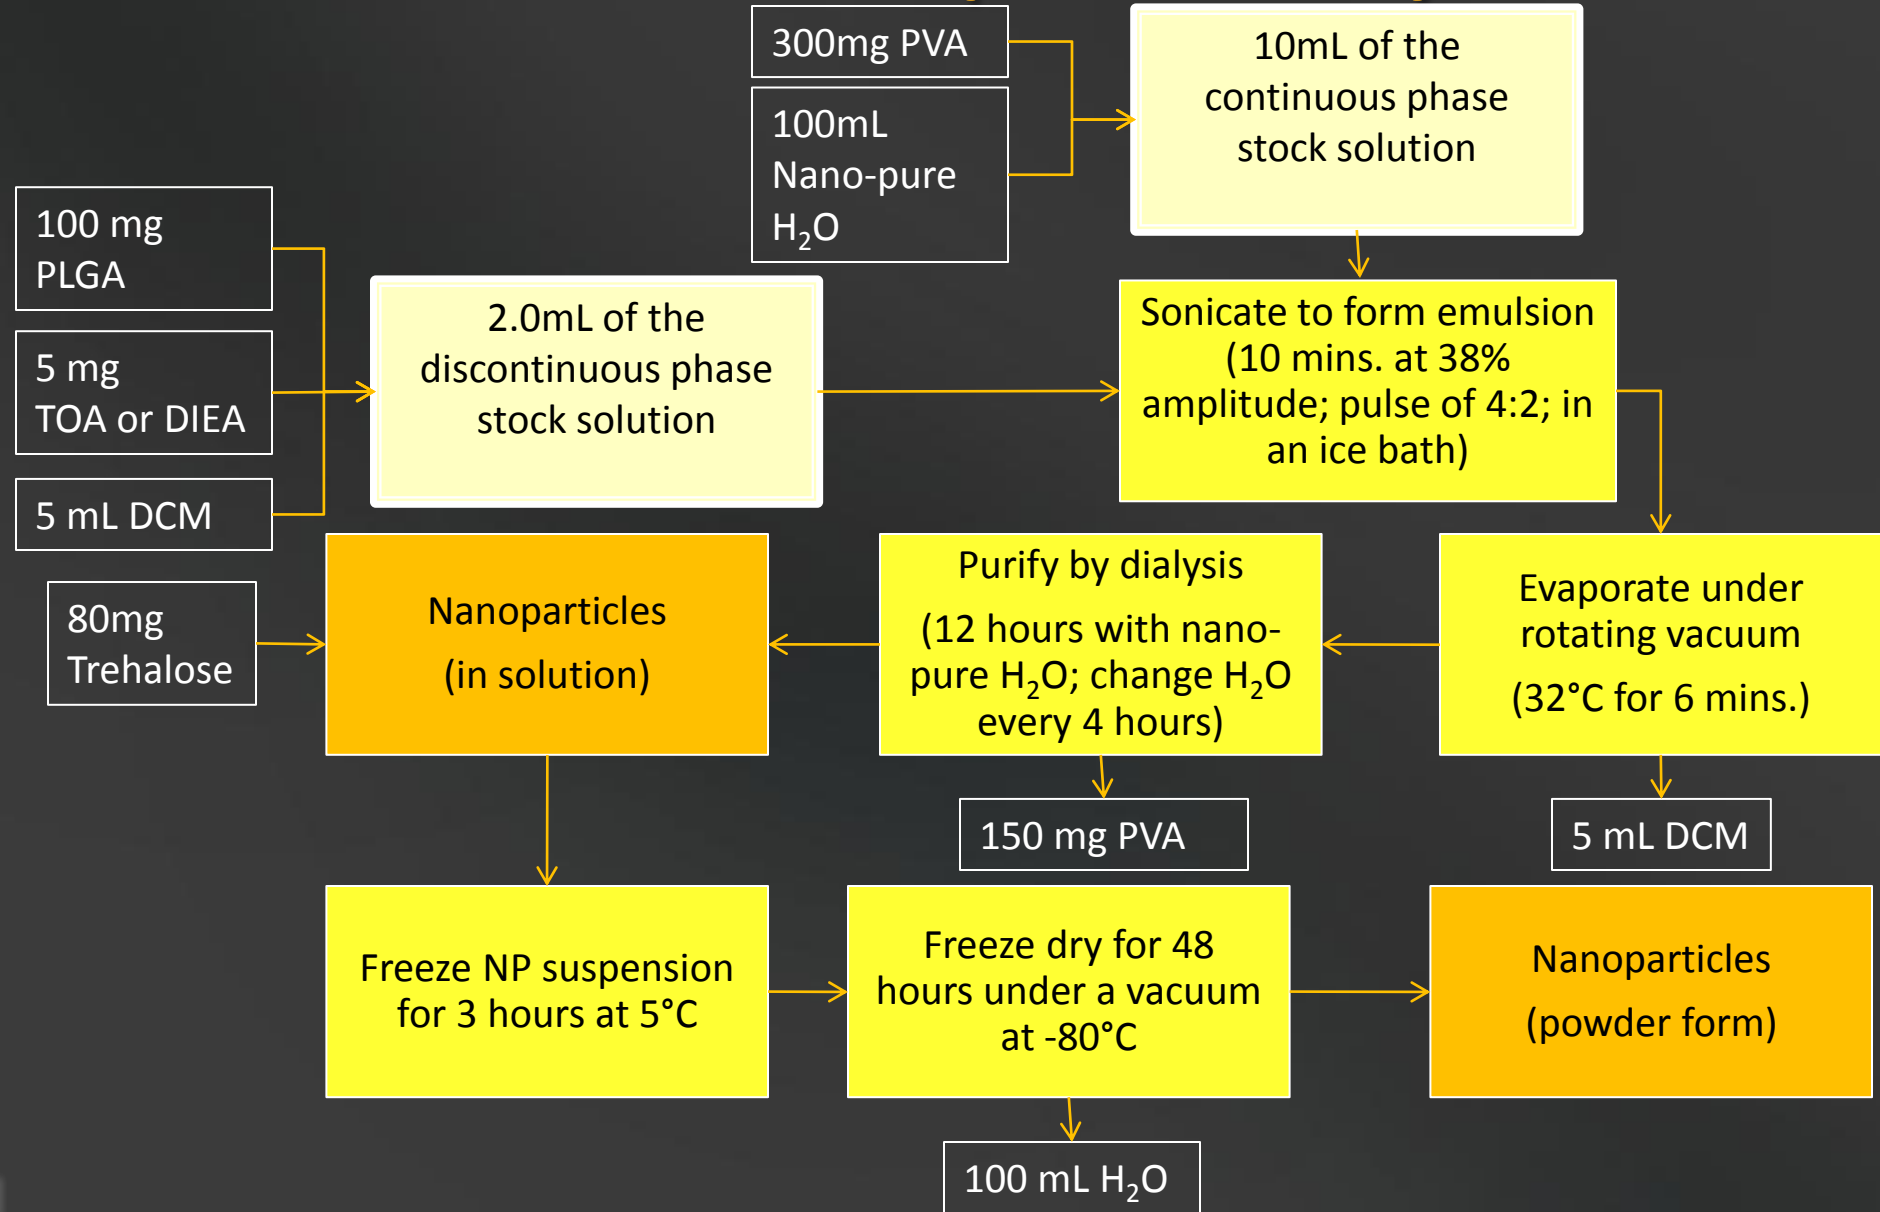

Organic solvent removal

Nanoparticles in solution and powder form

Loaded PLGA Nanoparticle Synthesis

Characterization – Blank NPs

- Average size

 - 216.3 nm

- PDI

 - 0.098

- Zeta potential

 - -21.7 mV

Characterization – Loaded NPs

- Average size

 - 213.1 nm

- PDI

 - 0.142

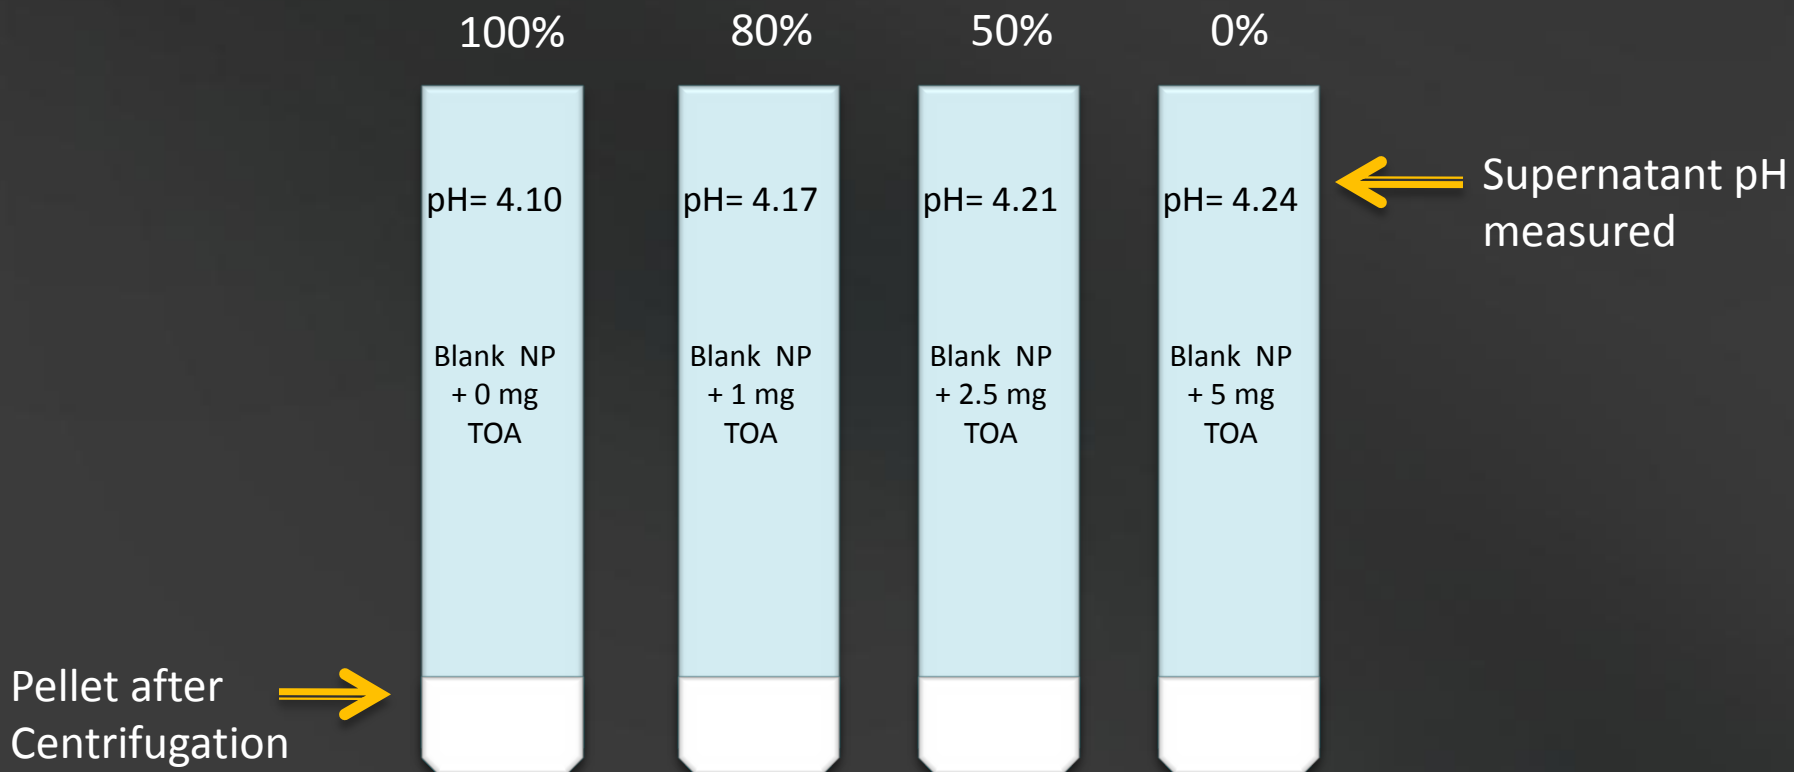

- Zeta potential

 - -8.4 mV

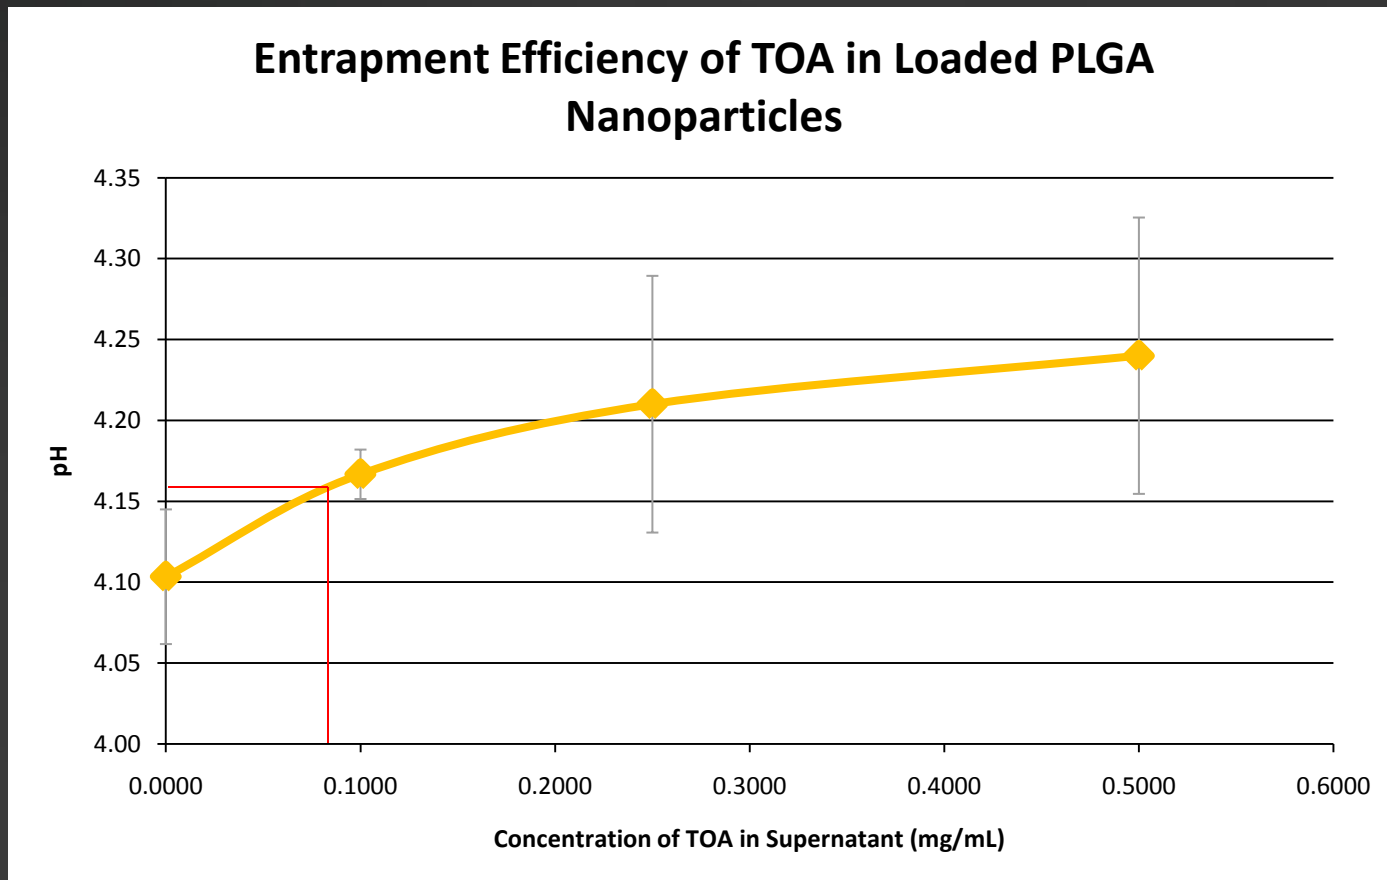

Entrapment Efficiency

- Standard curve of TOA concentration in supernatant vs. pH
- Procedure

Entrapment Efficiency

- Entrapment Efficiency (EE): 83%

Deactivation Reaction

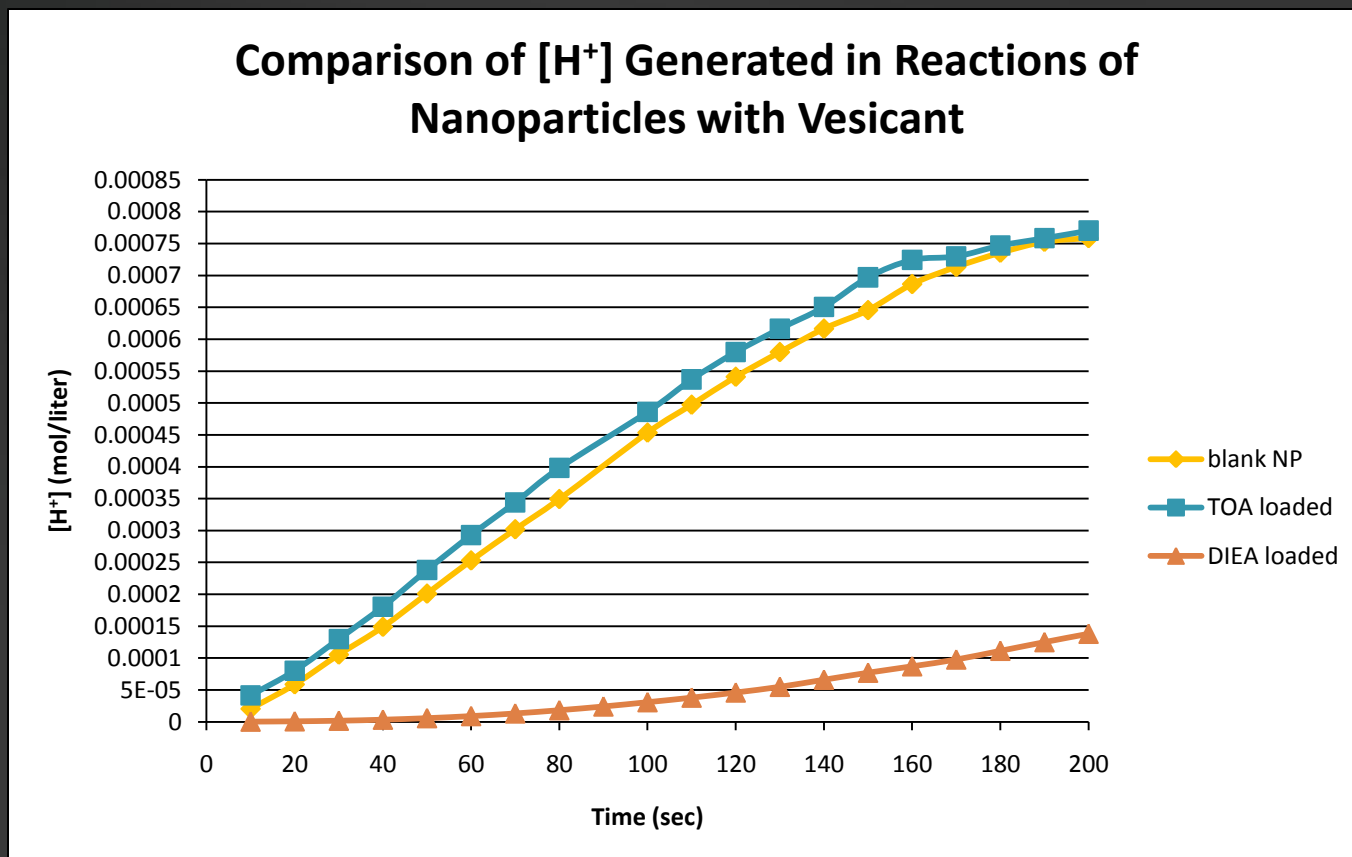

Reaction Testing - Free Chemicals

Profile of $[H^+]$ generated after introduction of vesicant to solutions of surfactant and deactivating chemicals.

Reaction Testing - Nanoparticles

Profile of $[H^+]$ generated after introduction of vesicant to solutions of nanoparticles loaded with deactivating chemicals.

Reaction Testing

Comparison of percent destruction of vesicant after introduction to various chemical and nanoparticle solutions.

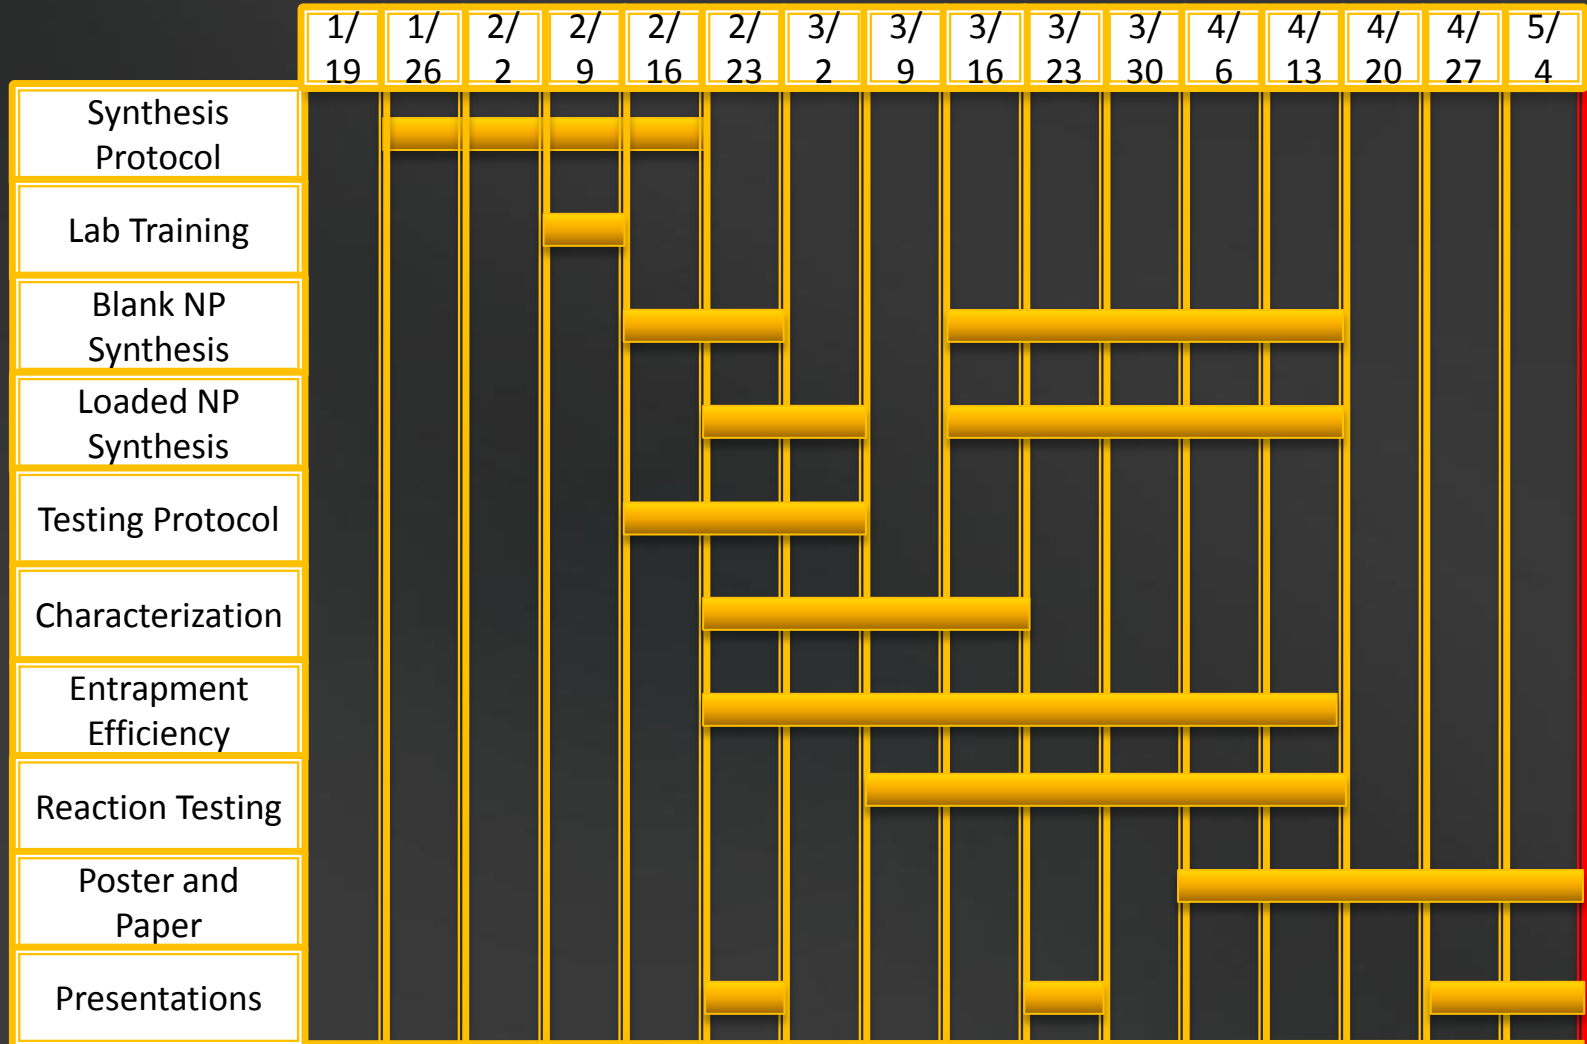

Budget

- Initial budget: \$700
- Chemicals ordered from Fisher Scientific and Sigma Aldrich
 - NP synthesis
 - Testing
- Characterization of NPs
 - TEM
 - DLS

Item	Cost
Fisher Scientific	\$198.54
Sigma Aldrich	\$528.14
Characterization	\$130.00
Total spent	\$856.68

Design Timeline

Weeks

Conclusion

- NP characterization showed successful synthesis results
 - Consistent with measurable objectives for size, polydispersity index, and zeta potential
- Entrapment efficiency of deactivating chemical was successfully determined
 - Consistent with measurable objectives
- Although no significant change was observed between the loaded and blank nanoparticles, reaction testing showed nanoparticles reacted faster than free deactivating chemical
 - Consistent with measurable objectives
